## 1 Chapter 1 - Introduction

**Step 0 in Estimation Theory is to model the data.** Before moving further into the details, we first discuss some commonly used mathematical tools.

A Parameterized Probability Distribution Function (PDF) is useful to analyse the model we create and is therefore a commonly used mathematical tool in the following chapters. A Parameterized PDF is of the form shown in equation 1 where  $g$  is some function of the random variable,  $x$  and some parameter,  $\theta$ . The PDF of a vector is the product of the PDFs of its elements.

$$\mathcal{P}\{x; \theta\} = g(x, \theta) \quad (1)$$

White Gaussian Noise is another commonly used tool to make the problem mathematically solvable. The PDF of White Gaussian Noise is given in equation 2 and the figure is plotted pictorially in figure 1. You can generate this yourself using the python code at this [GIT Repo](#). In fact, most of the figures and problems are documented [here](#).

$$\mathcal{P}\{x; \theta, \sigma\} = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left[\frac{-1}{2\sigma^2} (x - \theta)^2\right] \quad (2)$$

There are two general classes of estimators:

1. **Classical Estimators:** The Parameters to be estimated are Deterministic as shown in equation 3.

$$\hat{\theta} = g(x) \text{ where } \mathcal{P}\{x; \theta\} \text{ is the PDF of } x \quad (3)$$

2. **Bayesian Estimators:** The Parameters to be estimated are Random Variables and their moments are to be estimated. These are described in equation 4

$$\hat{\theta} = g(x) \text{ where } \mathcal{P}\{x|\theta\} \mathcal{P}\{\theta\} \text{ is the PDF of } x \quad (4)$$

An estimator is just a transform of one random variable to another. An estimator takes realization of a random variable and gives the best guess of the parameter that it was designed to estimate. An estimator boils down to a random variable which has a mean equal the parameter in question and with as low a variance as possible. This needs to be established using Monte Carlo simulations.
